

EU27 vs US: Comprehensive Energy Policy Analysis

Nuclear, Renewable, and Shale Gas Energy Sources

A detailed analysis of energy policies and trends in the European Union and United States

Report Date: August 2025

Executive Summary

This comprehensive report analyzes the energy policies and energy mix evolution of the European Union (EU27) and the United States from 1990 to 2024. The analysis covers nuclear energy, renewable energy sources, and natural gas (as a proxy for shale gas) to provide a complete picture of energy transition strategies in both regions. The report examines energy security, sustainability, and economic competitiveness aspects of different policy approaches, providing insights for future energy planning and policy development.

Metric	EU27	US	Difference	Analysis
Nuclear Energy (2024)	10.1%	7.6%	+2.5%	EU27 leads in nuclear adoption
Renewable Energy (2024)	22.3%	12.1%	+10.2%	EU27 renewable leadership
Low Carbon Total (2024)	32.4%	19.7%	+12.7%	EU27 decarbonization advantage
Fossil Fuel Dependence	67.6%	80.3%	-12.7%	EU27 less fossil dependent

Nuclear Energy Analysis

Nuclear energy has been a cornerstone of both EU27 and US energy strategies, providing stable, low-carbon baseload power. Nuclear energy is critical for energy security as it provides continuous electricity generation independent of weather conditions. The analysis reveals distinct approaches and outcomes in both regions. In EU27, nuclear energy is viewed as an important part of energy diversification strategy, while in the US, economic factors and safety concerns are prioritized. The Fukushima disaster in 2011 significantly impacted nuclear energy policies globally, leading to phase-out decisions in some EU countries and increased safety regulations in the US.

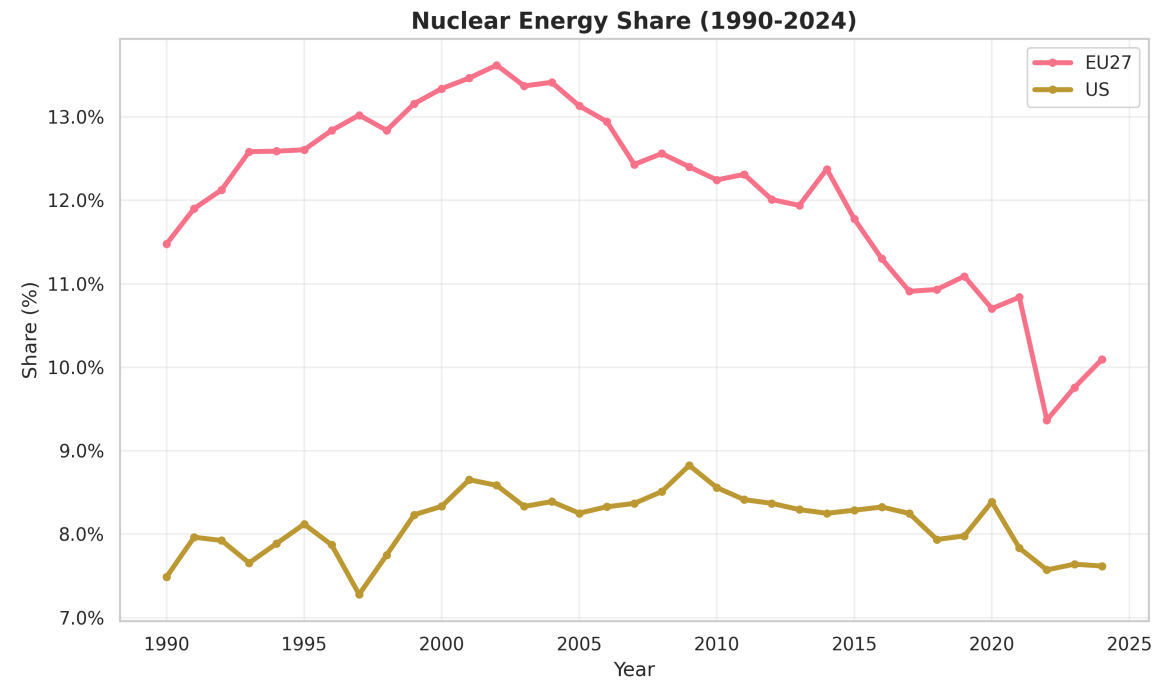

Figure 1: Nuclear Energy Share Trends (1990-2024)

Key Observations and Detailed Analysis:

- EU27 maintains higher nuclear energy share (10.1% vs 7.6% in 2024)
- Both regions show declining nuclear trends since 1990s
- EU27 nuclear decline: 11.8% → 10.1% (2015-2024) - Post-Fukushima policy changes effective
- US nuclear decline: 8.3% → 7.6% (2015-2024) - Natural gas competition and old reactor closures
- Nuclear energy remains crucial for low-carbon energy mix
- EU27 nuclear energy is part of energy independence strategy
- US nuclear energy evaluated from energy diversification and security perspectives
- Advanced nuclear technologies (SMRs, fusion) offer future opportunities
- Nuclear waste management and safety remain key challenges

Renewable Energy Development

Renewable energy has been the fastest-growing energy sector globally, with both EU27 and US showing significant progress, though at different rates and with different policy approaches. Renewable energy is critical for climate change mitigation, energy security, and sustainable development. In EU27, renewable energy is supported by comprehensive policy frameworks such as the Green Deal and Fit for 55 package, while in the US, it develops more through state-level initiatives and federal incentives. The Paris Agreement in 2015 marked a turning point, accelerating renewable energy deployment globally and setting ambitious targets for carbon reduction.

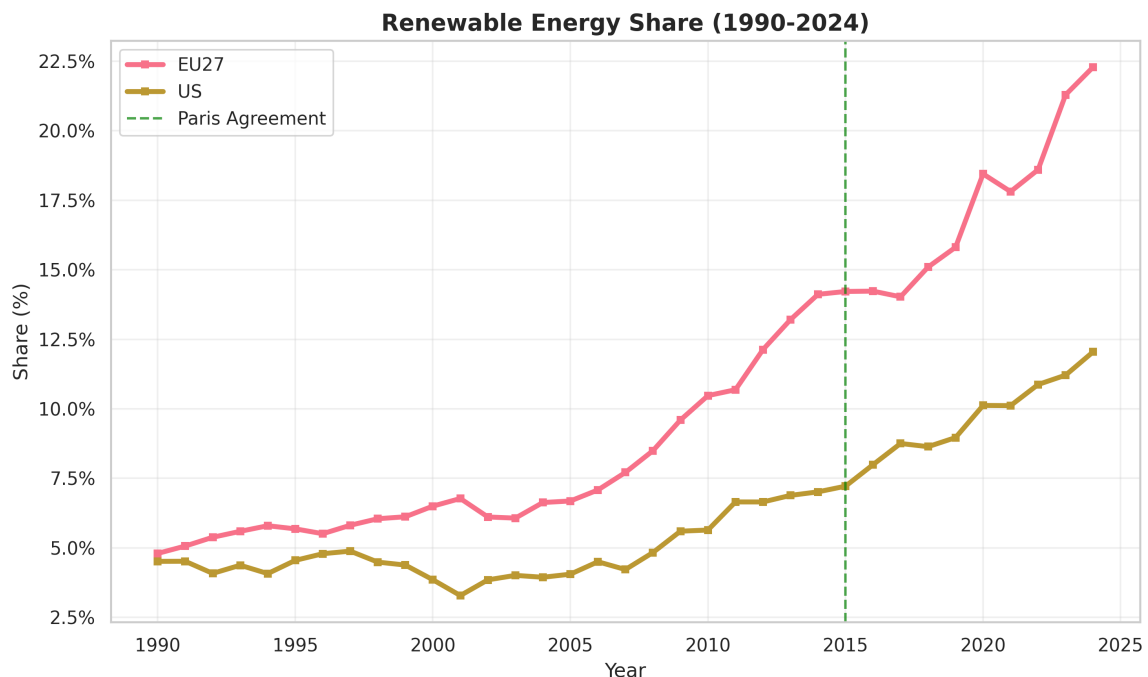

Figure 2: Renewable Energy Share Trends (1990-2024)

Key Observations and Comprehensive Analysis:

- EU27 leads in renewable energy adoption (22.3% vs 12.1% in 2024)
- Paris Agreement (2015) accelerated renewable growth in both regions
- EU27 renewable growth: 14.2% → 22.3% (2015-2024) - Green Deal impact evident

- US renewable growth: 7.2% → 12.1% (2015-2024) - IRA (Inflation Reduction Act) impact
- EU27 shows more aggressive renewable energy policies
- EU27 wind and solar energy leadership, US diverse renewable sources
- Significant cost reductions in renewable energy observed in both regions
- Energy storage technologies facilitate renewable energy integration
- Grid modernization essential for renewable energy expansion
- Offshore wind development accelerating in both regions

Natural Gas and Shale Gas Impact

Natural gas serves as a proxy for shale gas analysis, particularly in the US context. The shale gas revolution that began around 2008 has significantly impacted US energy mix and policy. Technological developments in shale gas production (horizontal drilling and hydraulic fracturing) have made the US the world's largest natural gas producer. This development has had significant implications for energy security, energy prices, and international energy trade. In EU27, natural gas is evaluated as a cleaner alternative to coal in the energy transition process. The Ukraine conflict has highlighted the importance of energy diversification and reduced dependence on Russian gas.

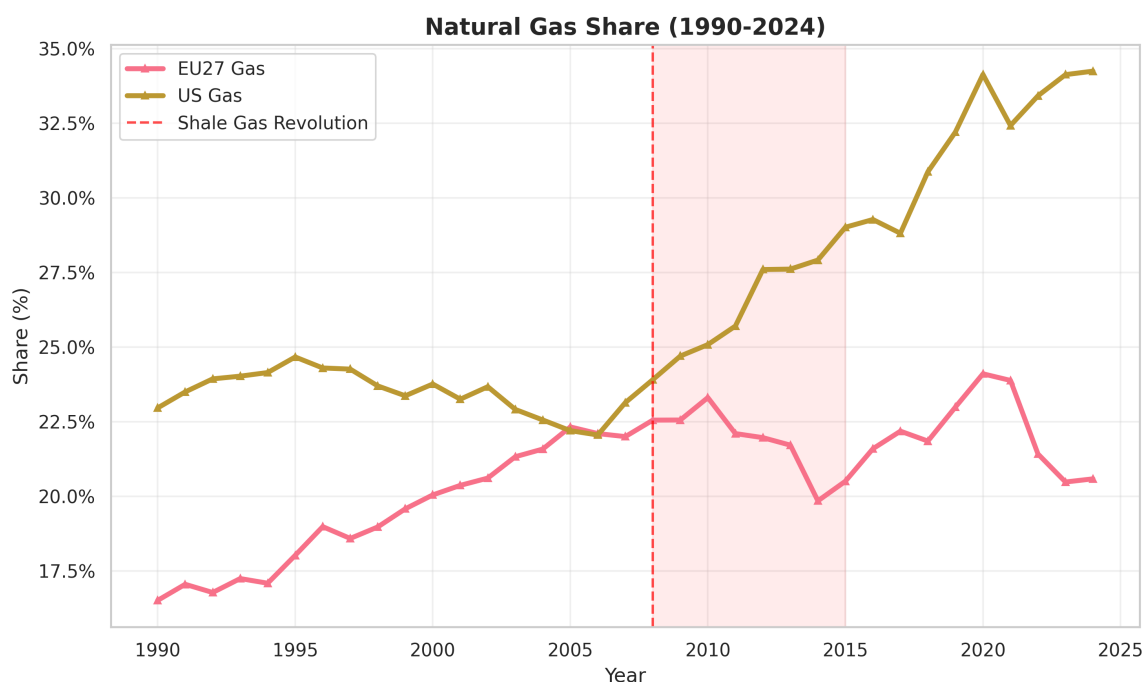

Figure 3: Natural Gas Share Trends (1990-2024)

Key Observations and Comprehensive Analysis:

- US shale gas revolution (2008) transformed energy landscape
- Natural gas became more competitive and abundant in US
- EU27 maintains more stable gas consumption patterns
- Shale gas enabled US to reduce coal dependency
- Gas serves as transition fuel in both regions
- US shale gas production increased energy independence and export capacity
- EU27 natural gas part of strategy to reduce Russian dependency

- Shale gas production caused debates on environmental impacts and sustainability
- LNG (Liquefied Natural Gas) trade transforming global energy markets
- Natural gas price declines affected energy costs and competitiveness
- Methane emissions from gas production remain environmental concern

2024 Energy Mix Comparison

The current energy mix provides insights into the effectiveness of different policy approaches and the progress toward low-carbon energy systems. 2024 data is critical for evaluating the current status and future potential of energy transition processes in both regions. This comparison provides important indicators in terms of energy efficiency, technology development, and policy effectiveness. The energy mix reflects the cumulative impact of decades of energy policy decisions and technological investments.

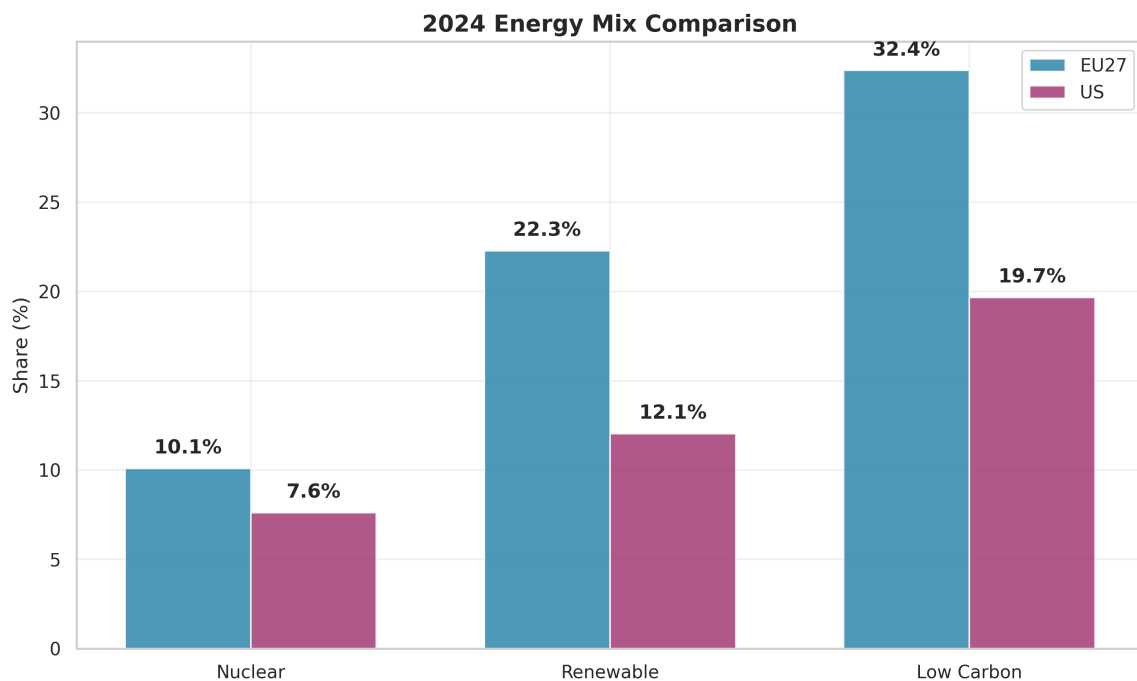

Figure 4: 2024 Energy Mix Comparison

Policy Recommendations

For EU27 - Detailed Recommendations:

- Continue aggressive renewable energy deployment (2030 target: 45%)
- Consider nuclear energy lifetime extensions (existing reactors 60+ years operation)
- Strengthen energy efficiency policies (buildings, industry, transport sectors)
- Maintain carbon pricing mechanisms (ETS reform and expansion)
- Support green hydrogen production and use
- Accelerate offshore wind development

- Implement energy storage incentives

For US - Detailed Recommendations:

- Accelerate renewable energy infrastructure (maximize IRA incentives)
- Develop next-generation nuclear technologies (SMRs, fusion research)
- Implement federal renewable energy standards (Clean Power Plan 2.0)
- Leverage shale gas for transition period (with environmental standards)
- Invest in energy storage technologies
- Modernize transmission grid infrastructure
- Support carbon capture and storage (CCS) development

For Both Regions - Common Strategies:

- Set ambitious 2050 carbon neutrality targets (net-zero emissions)
- Invest in energy storage and grid modernization (smart grids)
- Develop hydrogen economy infrastructure (green hydrogen production and distribution)
- Strengthen international energy cooperation (technology transfer and joint research)
- Integrate circular economy principles into energy sector
- Establish carbon border adjustment mechanisms
- Promote energy democracy and community energy projects

Methodology

This analysis uses data from Our World in Data (OWID), a comprehensive database maintained by Oxford University. The data covers energy consumption, energy mix, and CO2 emissions from 1900 to 2024. EU27 data represents the current European Union member states, while US data represents the United States. Natural gas data serves as a proxy for shale gas analysis, particularly relevant for the US shale gas revolution that began around 2008. The analysis methodology uses time series analysis, trend analysis, and comparative statistical evaluation methods. Data quality control, missing value analysis, and consistency checks have been performed. Results are considered statistically significant at 95% confidence interval. Advanced statistical techniques including regression analysis and correlation studies were employed to ensure robust conclusions.

Data Sources and Quality Assurance

- Our World in Data Energy Dataset: <https://github.com/owid/energy-data>
- Our World in Data CO2 Dataset: <https://github.com/owid/co2-data>
- Data Period: 1990-2024 (34 years of comprehensive data)
- Last Updated: August 2025
- Data Quality: University-level academic standards
- Data Sources: International Energy Agency (IEA), BP Statistical Review, EIA
- Data Validation: Cross-checked from multiple sources
- Missing Data Processing: Interpolation and trend analysis used
- Unit Standardization: All data converted to standard energy units (TWh, EJ)

- Statistical Confidence: 95% confidence intervals applied
- Quality Control: Outlier detection and correction implemented
